

Aiken's 1st law:

A mixed layer, is a mixed layer, is a mixed layer

Definition: A Mixed layer is a layer of constant density, at any depth: surface; bottom; mid-depths.

Other than a 'freak', this comprises a layer of constant Temperature & Salinity.

Processes are:

1. Density-driven, convectational cooling: in winter, surface water overturn or at night convectational overturn (every night, if atmosphere colder than ocean).

Mainly surface layers, but density driven processes operate throughout the water column and everywhere.

Surface layers of low salinity (from precipitation) can be mixed, but are a restriction on deeper mixing.

2. Tidal mixing in shallow areas, principally the shelf seas (estuaries).

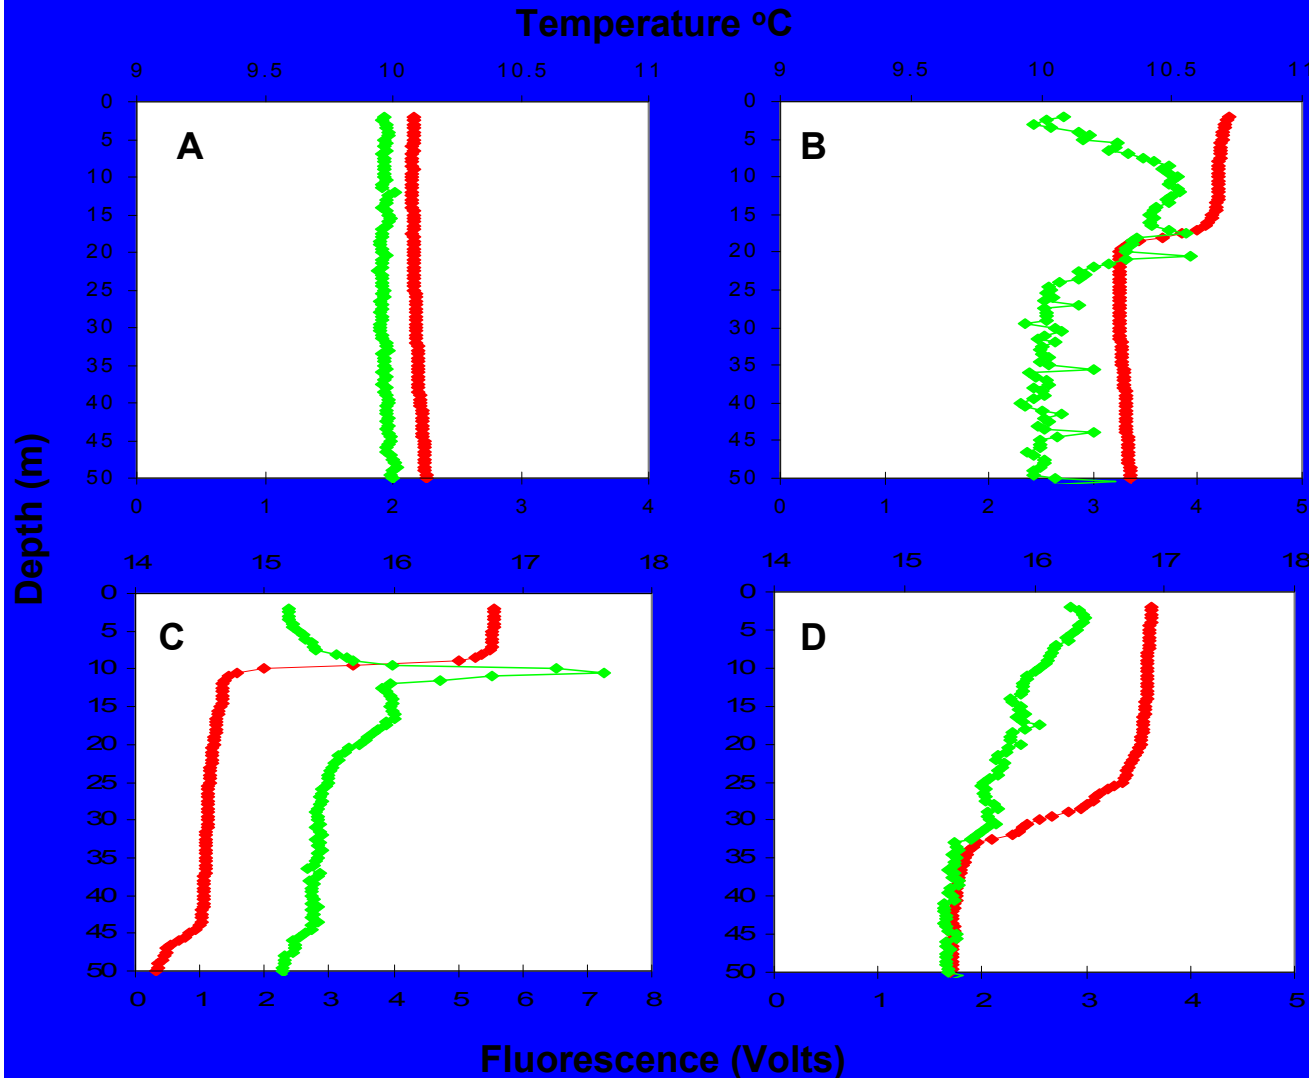

Bottom-up mixing, all year in shallow layers with strong high tides, and bottom mixed layers in seasonally stratified shelf regions. (Pingree h/u^3)

3. Wind-mixing of surface waters, occurs everywhere, but episodic; - no wind, no mixing - surface stratification by day, but eroded at night.

Examples of patterns of stratification at L4 in WEC: winter; spring summer; late autumn.

UOR measurements of temperature and chlorophyll fluorescence from north to south across the Arctic front on 19 August 1986.

WTP?

The point is, if there is a simple model for vertical physical structure, we can infer a simple model for vertical biological structure:

Shelf seas - Surface Mixed Layer / Thermocline / Bottom mixed layer

Ocean - SML / seasonal thermocline / permanent thermocline

Shelf or Ocean Biological structure:

-SML with mixed biomass (possible maximum at surface);

- or there may be a biomass maximum in the thermocline.

Aiken's 2nd law

If you can't see it from space it is not important

No controversy – surface observations of roughness from SAR and altimeter.

Transfer of atmospheric radiatively-active and biogenic gases:

O₂, N₂, CO₂, etc

N₂O, CH₄, DMS, COS, SO₂, VOCs etc

PAR = 38 μE ; < 2 % surface
- c) 15xx: 16 09 S; mld = 130 m;
PAR = 40 μE ??

WTP?

Remote sensing missions are global, daily, long-term and provide data ideal for Earth system science problems; we must exploit these.

The surface ocean (SML) is the interface between the ocean C-cycle and the global C-cycle (atmosphere) and diagnosis of the biogeochemistry of this layer is the important part of air-sea and sea-air interactions.

There can be a missing fraction below the surface layer that may be important for shallow layers, particularly in the shelf seas.

Deep sub-surface Chla layers at >100 m ($< 0.1\%$ surface PAR) are not important.

HAVE NO FEAR – SUPERMODEL IS HERE!!

We have the Taylor, Harris, Aiken (1986) model!!

Taylor, Harris, Aiken (1986) Time-dependent, 1D, 1P, 1N Model

$$\frac{\delta P}{\delta t} = [\alpha(I)\phi(N) - m]P - v\frac{\delta P}{\delta z} + \frac{\delta}{\delta z}[K(z,t)\frac{\delta P}{\delta z}]$$

$$\frac{\delta N}{\delta t} = -\gamma[\alpha(I)\phi(N) - \varepsilon m]P + \frac{\delta}{\delta z}[K(z,t)\frac{\delta N}{\delta z}]$$

$$\alpha[I] = \alpha_0 P_m \tanh\left(\frac{\alpha I}{P_m}\right) (\alpha I / P_m)$$

Jassby & Platt, 1976, $\alpha(z)$ is the specific growth rate

$$\frac{\delta I}{\delta z} = k(I)$$

$k = 0.10 + 0.18 P(z,t)$; $I = I_0 e^{-kz}$; $k = k_w + k_c C_{\text{CHL}} + \dots$;

$$\phi(N) = \frac{N}{N + v}$$

Michaelis–Menten ; $v = 0.05, 0.2, 0.8 \text{ mM N m}^{-3}$; MacIsaac & Dugdale (1968)

**where P is the abundance of Phytoplankton at depth z
 v is the sinking speed
 $K(z)$ is the turbulent eddy diffusion coefficient**

Devised to simulate the ‘quasi steady state’ vertical structures of temperature and Chlorophyll concentration measured by UOR in stable areas such as central Celtic Sea.

Taylor, Harris, Aiken (1986) model results:

- a. Vertical profiles in 'steady state' numerical analysis
- b. Steady state 'Shelf', 'Ocean' and analytical '2-layer' analysis.

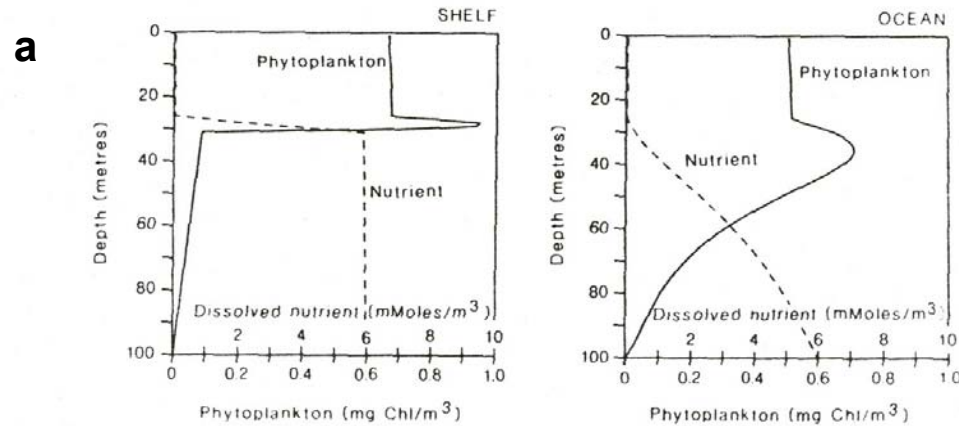

Fig. 1 Vertical profiles of phytoplankton and nutrient after 100 days under shelf or oceanic turbulence conditions (see text), with $v = 0.2$ mM per cubic m, $m = 0.078$ per day and $\epsilon = 0.2$.

Steady-state, 2-layer analysis

$$P_m/P_t = (m - \Theta_t + q_3)/q_2$$

$$\Theta_t = \alpha_t [N_{to}/(N_{to} - v)]$$

α_t = light dep rate of photosynthesis

q (and s) are transfer terms (constants)

P_m from satellite

Calculate P_t from P_m/P_t

Aiken's 3rd law

**Every oceanographer should be a modeller
and every modeller should go to sea.**

Scientific method: make observations, derive empirical relationships, look for mechanisms, processes, formulate rules and hypotheses, test with observations.

THA model was devised to show how the physical structure (in shelf seas) regulated the vertical structure of phytoplankton biomass (chlorophyll) from observations of T, Chla from UOR tows.

AMT observations provide data of diverse ecosystems (biogeochemical provinces) with different patterns of stratification, nutrient status, characteristic flora (phytoplankton assemblages) and bioenergetics.

Added observations from process studies:

BOFS/JGOFS; L4 seasonal; Arctic and Antarctic studies; Benguela.

Different ecosystems (different flora) function differently in different locations.

What is in common?

What is universal?

What is distinct?

MODELS

Musings on Models, PFTs, Remote sensing of PFTs

Modelling biogeochemical cycling by phytoplankton (e.g. C, N, P, S, Ca cycles) in aquatic ecosystems is crucial to quantifying and understanding the Earth System & climate change.

Models need realistic representation of complex bio-mechanistic processes; use of Plankton Functional Types to describe ecosystem functioning is logical.

The functional properties of phytoplankton (ecological, photosynthetic) and their bio-optical traits, provide functional relationships for derivation of Phytoplankton Functional Types (PFTs) from remotely sensed ocean colour.

Environmental differences (light, nutrients, T, S, turbulence, stratification, seasonality) between ecosystems force phytoplankton diversity and seasonal succession.

BIOMES, PROVINCES.

Phytoplankton dynamics can only be understood by contextual correlation with environmental factors: physical (turbulence, stratification, clines), chemical (nutrient availability) and radiant energy (light climate, photon flux).

Diagnosis of PFTs from remotely sensed data of Ocean Colour

The functional properties of phytoplankton (ecological, photosynthetic) and their bio-optical traits (BOT), provide functional relationships for derivation of Phytoplankton Functional Types (PFTs) from remotely sensed ocean colour.

1. Phytoplankton Bioenergetics (photosynthesis) – BOT?
2. Bio-optical traits derive from Phytoplankton pigments (Chla, carotenoids) – taxa-specific pigments?

CHLOROPHYLL, pigments, optical properties

Chlorophyll-a, -b, -c, the carotenoids (PSC & PPC) + phycobillins (low abundance in surface) colour the surface ocean.

Chlorophylls are cyclic tetrapyrroles, with N ($C_{55}H_{72}N_4O_5Mg$)

Chla has distinctive strong blue absorption 'soret' band (~400-470 nm, centre ~443 nm) and secondary absorption peak at ~675 nm.

Xanthophylls (carotenoids, Fuc, Per, Hex, Lut, Zea) are carbohydrates formed from carotenes (hydrocarbons)

Carotenoids have identical chromophores and very similar blue-green absorption spectra (~400-550 nm, peak ~490 nm) – no BOT from Carotenoids!!!

Chla needs 'N'; Carotenoids do not use 'N'.

Chla has distinctive 'blue' spectra: concentration of Chla has greatest influence on phytoplankton spectra in blue-green.

Functional classification of the Phytoplankton: PFTs

Alignment of phytoplankton size classes (Pico, Nano, Micro) with environmental niches (nutrient availability and light climate) and their photosynthetic capacity or bio-energetic status:

Microplankton bloom in high nutrient environments (upwelling zones, spring and summer blooms at temperate and sub-polar latitudes).

Nanoplankton grow in regions with some inorganic nitrogen & re-cycled nutrients (inorganic and organic).

Picoplankton survive in low nutrient environments (permanently stratified oligotrophic gyres)

Pico (prok) have low Chl-a, low TChla/Tpig, low Tot-carbon, Chl-a/C & low PQE;

Nano (flag) have med Chl-a, med TChla/Tpig, med Tot-carbon, Chl-a/C & med PQE;

Micro (D+d) have high Chl-a, high TChla/Tpig, high Tot-carbon, Chl-a/C & hi PQE.

WEALTH OF AMT DATA SUPPORT THESE OBSERVATIONS:

Plankton: Zubkov, et al 1998, 2000; Tarran et al 2006; Heywood et al 2006.

Pigs: Gibb et al, 2000; Barlow et al, 2002, 2004; Poulton et al, 2006; Aiken et al 2008

Productivity: Maranon & Holligan, 1999; Maranon et al, 2000, Maranon, 2005.

Scaling of Photosynthesis & cell size: Maranon et al 2007, Maranon, 2008

Maranon 2008
JPR, in press

Scaling of phytoplankton
photosynthesis and cell size in
the ocean.

Functional classification of the Phytoplankton: PFTs

Conventionally phytoplankton classified by size:

Picoplankton (typically $< 2 \mu\text{m}$) pico-prokaryotes (cyanobacteria) + pico-eukaryotes;

Nanoplankton ($\sim 2\text{-}20 \mu\text{m}$) eukaryote flagellates (prymnisiophytes etc)

Microplankton ($20\text{-} >200 \mu\text{m}$) mostly diatoms and dinoflagellates

These ranges are not Robust: diatoms range from $5 \mu\text{m}$ 2 mm (whole nano range);
some flagellates $< 2 \mu\text{m}$ (pico-eukaryotes).

ERSEM has bacteria, heterotrophs, zooplankton, 4 phytoplankton:

Picoplankton, flagellates, dinoflagellates and diatoms.

DGOM (LeQuere et al., 2005) has 10 functional types: bacteria, 3 zooplankton and 6 phytoplankton arranged by size class:

PICO - (pico-autotrophs, prochlorophytes, cyanobacteria, N_2 -fixers, pico-eukaryotes);

NANO - Calcifiers (coccolithophores); DMS producers (e.g. *Phaeocystis* spp); other nano-flagellates;

MICRO - Silicifiers (Diatoms); others (Dinoflagellates).

Currently there is no consensus, systematic definition of PFTs.

**Phytoplankton size groups, taxa specific, diagnostic pigments.
Diagnostic Pigment method Claustre, 1997; Vidussi, 2000; Uitz, '06.**

Taxa specific pigments:

Micro-plankton

Diatoms: FUC;

Dinos: PER; not present in all Dinos (replaced by FUC)

Nano-plankton (various flagellates)

Prymnisophytes: HEX

Chrysophytes: BUT

Cryptophytes: ALLO

Many nano-Eukaryotes also have Chlb (ambiguity with prochlorophytes)

Pico-plankton (prokaryotes + pico-eukaryotes)

Prokaryotes (*synechococcus* & *prochlorococcus*): ZEA

Pico-eukaryotes are flagellates with HEX, BUT pigments (anomalies)

Pico-Eukaryotes prochlorophytes: Chlb

Caveats: PER not present in all Dinos (replaced by FUC)

FUC is pre-cursor pigment for HEX & BUT and always co-exists.

Phaeocystis (flagellate) has HEX when in single cell populations (ss Chla max) but has

FUC when in colonial bloom (> 2 mg.m⁻³)

Not definitive, many ambiguities, many exceptions!!!

Functional Classification of Phytoplankton: Phytoplankton Functional Types, PFTs Or Phytoplankton Size Classes, PSCs.

NS = No SeaWiFS; Benguela too close to coast for 9 x 9 km composite

**8-year time series from Sea WiFS, 1998-2006 for 6 ocean basins:
Pico plankton in oligotrophic gyres – upward trend??
More biomass or larger gyres, greater area of permanent stratification**

8-year time series from Sea WiFS, 1998-2006 for 6 ocean basins: Nanoplankton and microplankton (x5) - downward trend??

NOMAD, a_{ph} model: Conclusions

- a_{ph} model needs true validation vs phytoplankton species counts and AFC carbon.
- Satellite ocean colour provides a_{ph} at discrete wavelengths (443, 490, 510) that can be used for derivation of PSCs.
- The model uses only 1 variable a_{ph443} or S so the number of error sources are minimal.
- Implementation is simple so large data sets can be processed easily and quickly, providing capability to determine trends in oceanic ecosystems.
- Refinements of the model can provide further partitioning of PSCs.

Musings on Models, PFTs, Remote sensing of PFTs

Modelling biogeochemical cycling by phytoplankton (e.g. C, N, P, S, Ca cycles) in aquatic ecosystems is crucial to quantifying and understanding the Earth System & climate change. **NOMAD study - PSCs.**

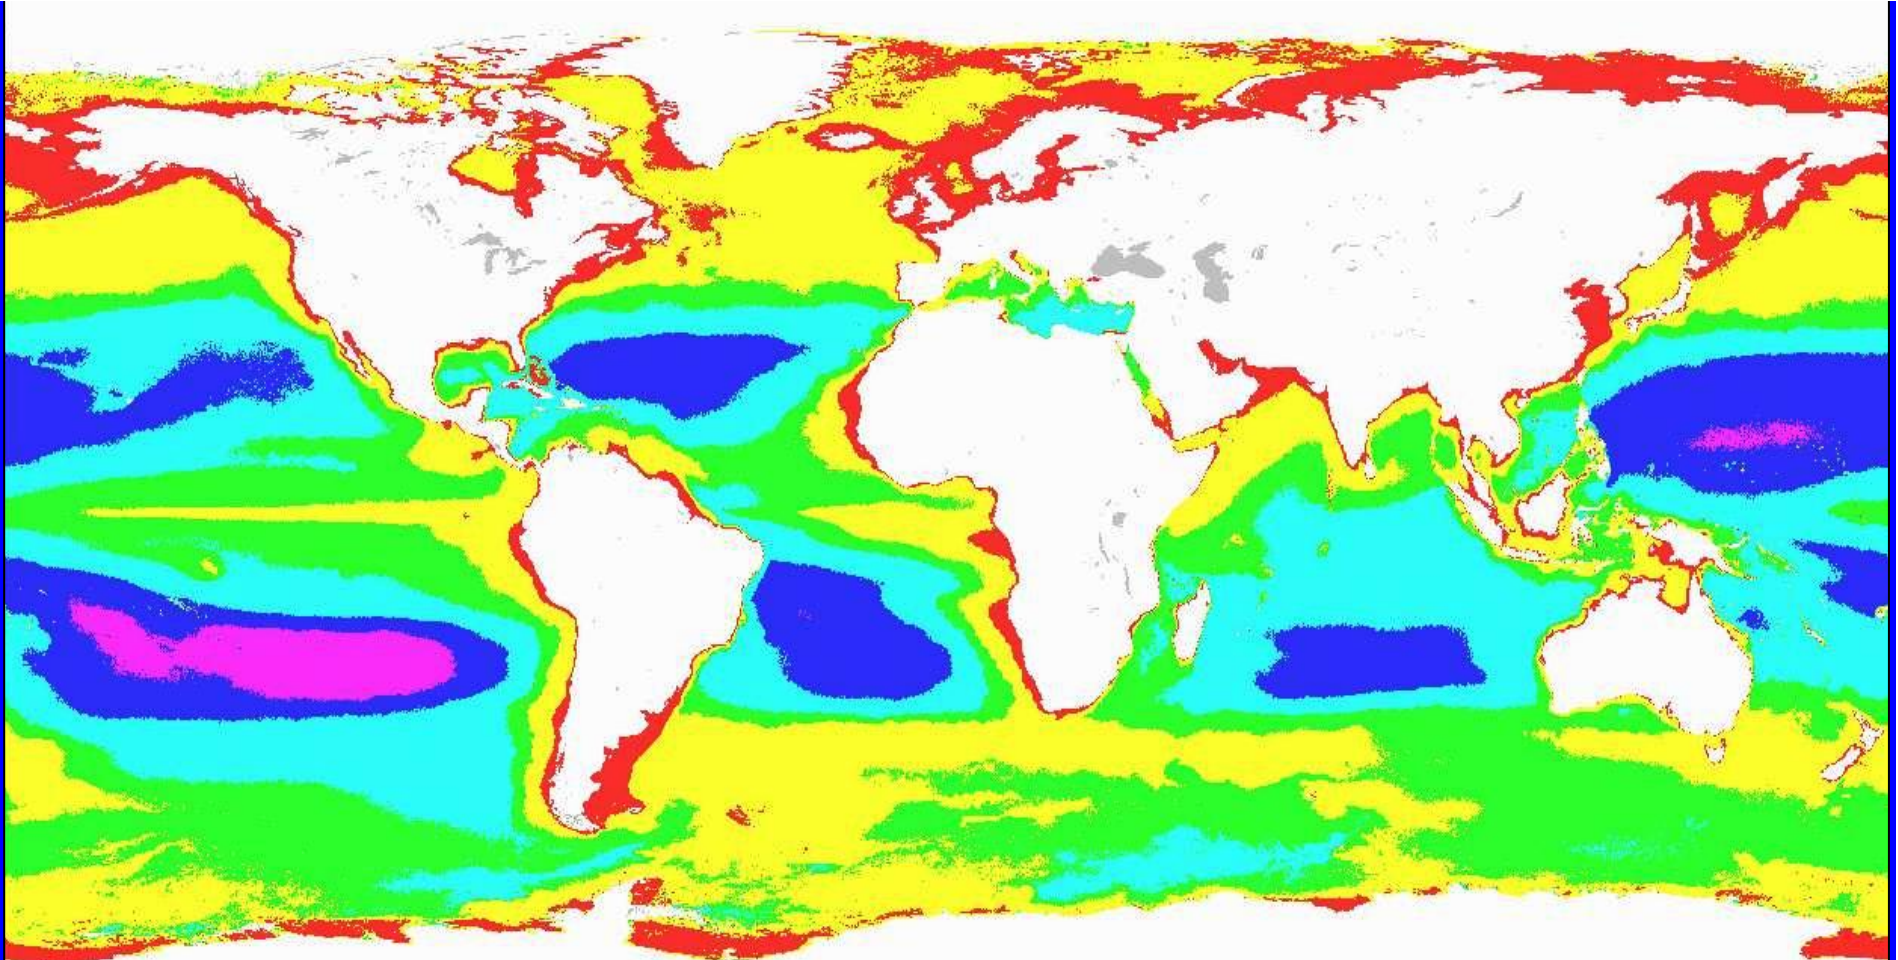

Models need realistic representation of complex bio-mechanistic processes; use of **Plankton Functional Types to describe ecosystem functioning is logical.**
YES – NOMAD study

The functional properties of phytoplankton (ecological, photosynthetic) and their bio-optical traits, provide functional relationships for derivation of Phytoplankton Functional Types (PFTs) from remotely sensed ocean colour.

Environmental differences (light, nutrients, T, S, turbulence, stratification, seasonality) between ecosystems force phytoplankton diversity and seasonal succession.
BIOMES, PROVINCES. **Yes – Hardman-Mountford et al**

Phytoplankton dynamics can only be understood by contextual correlation with environmental factors: physical (turbulence, stratification, clines), chemical (nutrient availability) and radiant energy (light climate, photon flux).

Bring it all together

from Hardman-Mountford et al (in press)

Classification of biomes from a hierarchical cluster analysis of global mean Chl a (SeaWiFS 1998-2004 average):

Oligotrophic cluster cyan, blue and magenta (sub-clusters);

Mesotrophic cluster yellow and green (sub-clusters);

Eutrophic cluster shown in red;

From SeaWiFS analyses, Oligotrophic ~63%, Meso ~35%, Eutrophic ~2%

**The big Earth System questions are:
How is the Earth changing and what are the
consequences for life on Earth?**

**Global Carbon cycle and the climate system are intimately linked
with the ocean C-cycle through the air-sea exchange of CO₂**

**PAST: the carbon cycle and climate of the Earth System have been tightly
coupled through the glacial-interglacial cycles and since.**

- but the mechanisms behind this coupling are not well understood

**PRESENT: human-induced changes in the contemporary carbon cycle have
great relevance to climate change policies and agreements. (e.g. Kyoto Protocol)**

- but current sources and sinks of carbon are poorly quantified

**FUTURE: carbon cycle feedbacks will have a significant influence on
climate change over the next 100 years**

- but the magnitude of these feedbacks are highly uncertain

For the Marine Environment, surface ocean-lower atmosphere, the questions are:

How do marine systems vary with time? (e.g. changes of THC, etc?)

How are marine ecosystems regulated by ocean processes? (physics, structure)

How do marine ecosystems interact with the global carbon cycle? (CO₂ flux)

Ocean circulation, currents, stratification, surface properties and ocean biogeochemistry, all **regulate the Air-Sea fluxes of CO₂** often separated in **TIME** and **SPACE**.

We can understand change in marine systems from:

1. Observations – observatories, WCO, AMT, other time series, other seasonal cycles.

2. Remote sensing observations.

3. Modelling, coupled circulation-ecosystem models with realistic ecosystem models, having representative PFTs

Is there a functional link between PQE and Chla/Tpig?

Log-linearly with Chla.

How will marine ecosystems change? Ecosystem Change Associated with Global Warming; interaction with global C-cycle.

5. BE-BOT hypothesis

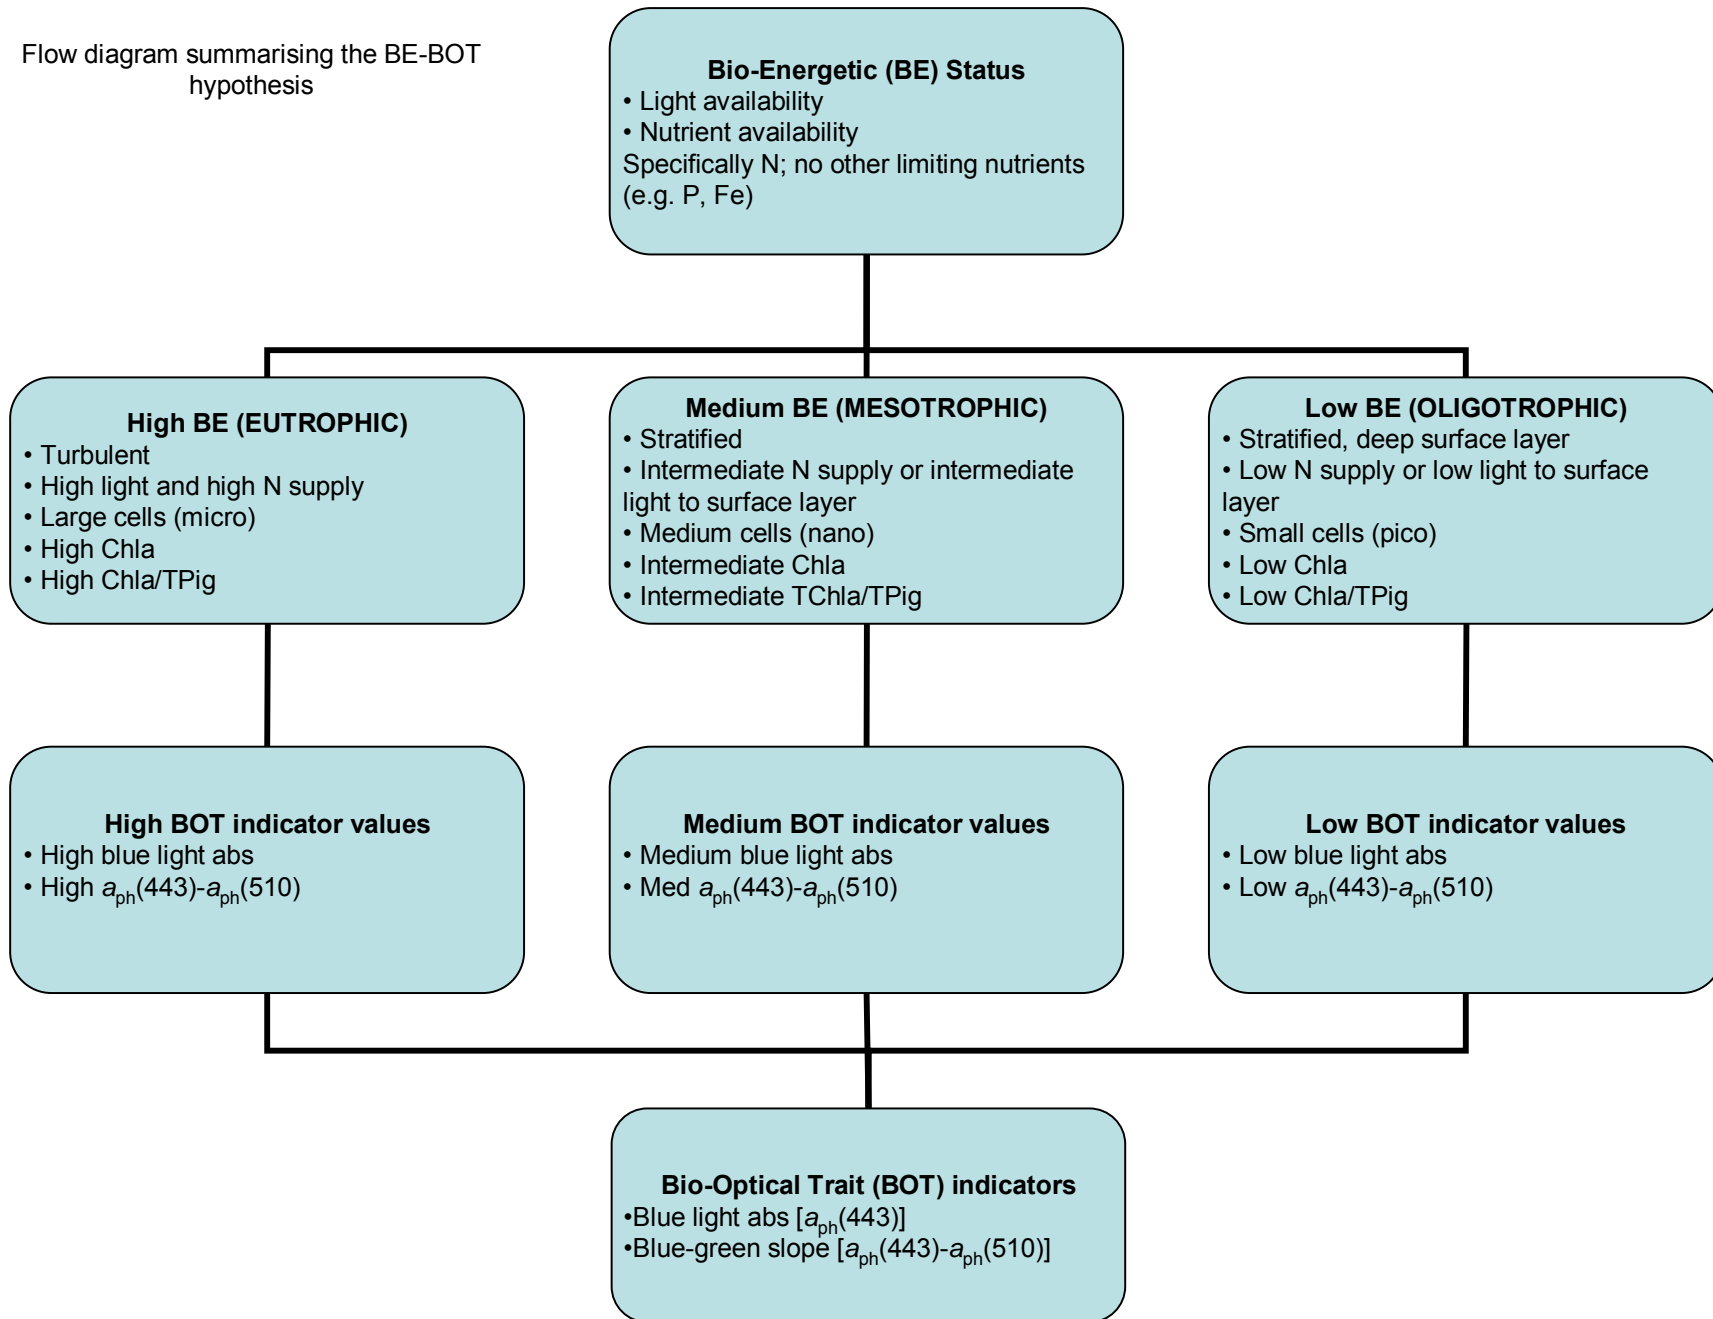

The bioenergetics of photosynthesis, coupled to environmental properties (nutrients, light fluxes, etc), is the definitive phytoplankton functional process that determines phytoplankton taxa, size classes and ecosystem trophic status, and that BE status is quantitatively linked to phytoplankton bio-optical traits (BOT) that are specific properties of phytoplankton size and taxa.

Specific BOT are conferred by the unique absorption spectrum of Chla (blue, 400-470 nm in vivo) that is distinct from carotenoid (PSC+PPC) absorption spectra (blue-green, 400-550 nm, peak ~490 nm).

A corollary of this hypothesis is that ocean IOPs, determined in situ or from ocean colour, are primarily a function of phytoplankton photosynthetic activity, through the instantaneous absorption of solar radiation (akin to action spectrum) and secondarily a function of the steady state biomass, (approximated by Chl-a determined in vitro from phytoplankton absorption or pigment analyses

Pigments, pigment-protein complexes, PSI, PSII and LHC are synthesised much slower, over 12-24 h and are cumulative from photosynthetic activity over the previous few days.

Flow diagram summarising the BE-BOT hypothesis

**Oligotrophic Ocean: 63% of global ocean ($\text{Chla} < 0.25 \text{ mg.m}^{-3}$);
Pico-plankton, prokaryotes (synechococcus; prochlorococcus)
and pico-eukaryotes (pico-eukaryotes)**

**Mesotrophic ocean, 35% of global ocean ($\text{Chla} > 0.25 - \sim 1.25$)
Nano-plankton, mostly flagellates (prymnesiophytes etc)**

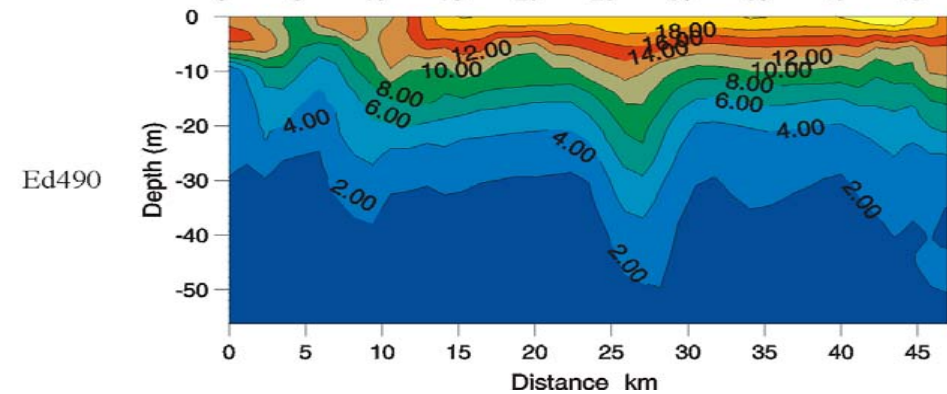

**Eutrophic Ocean, $\sim 2\%$ ocean ($\text{Chla} > \sim 1.25$)
Microplankton, mostly diatoms & dinoflagellates**

**Chla concentrations from SeaWiFS data; agrees with the
published data (e.g. Morel et al.)**

PHOTOSYNTHESIS, fluorescence, BIOENERGETICS

The quantum efficiency for C-fixation, φ or photosynthetic quantum efficiency (PQE) derived from Fv/Fm measured by fast repetition rate fluorometry (FRRF, Suggett *et al*, 2004; Rottgers, 2007) are closely related to bioenergetic (BE) status.

Bioenergetics is the transformation of light energy (photosynthesis) through intermediate stages to the synthesis of plants (Govindjee 1975), regulated by macro & micro nutrient quality and availability, or by photon flux if light limits.

Productivity 'P' (mols C m⁻³ d⁻¹) while dependent on BE status, is driven by light energy, E_{PAR}:

$$P = \varphi a_{ph} E_{PAR} \quad (\text{Marra et al, 2000});$$

or comparably

$$P = \text{const PQE } \sigma_{PSII} E_{PAR} \text{ Chla} \quad (\text{Suggett et al, 2001; 2004; Smyth et al, 2004});$$

Neither expression includes nutrient concentrations explicitly, inferring nutrient regulation of PQE, σ_{PSII} or φ , probably through the synthesis of protein-pigment complexes in the light harvesting complex (LHC) and photosystems (PSI, PSII).

The system is fuelled by N (& P, but rarely limiting).
